1 Problem Statement

Given a graph $G = (V, E)$, with vertices V, edges E, a source vertex s, a target vertex t, and edge weights $c(uv)$, where each weight $c(uv) > 0$ represents the cost associated with traveling from vertex u to v or from v to u, the objective is to find the shortest path from s to t such that the total cost of the path is a multiple of a given positive integer k.

2 Algorithm

The proposed algorithm is based on modifying the graph and applying Dijkstra's algorithm. Here's the pseudocode:

Algorithm 1 ShortestPathWithMultiplesOfK(G, s, t, k)

1: Let R be the set $\{0, 1, 2, ..., k-1\}$
2: Define a new graph $G' = (V', E')$
3:    where $V' = V \times R$
4: $E' := \{(u, r) \to (v, (r + c(uv)) \mod k) | (u, v) \in E, r \in R\}$
5: Weight of each edge $(u, r) \to (v, r')$ is $c(uv)$
6: Apply Dijkstra's algorithm on G' with source vertex $(s, 0)$
7: **return** shortest distance from $(s, 0)$ to $(t, 0)$

---

3 Implementation

Below is the C++ implementation of the algorithm:

```
// Code snippet: https://pastebin.com/Q1EU9tFc
```

4   Time Complexity

The time complexity of the algorithm is $O(E' \log V') = O(mk \log(nk)) = O(m \log n)$, since k is treated as a constant factor.
